Abstract

Automated photo tagging has established itself as one of the most compelling applications of deep learning. While deep convolutional neural networks have repeatedly demonstrated top performance on standard datasets for classification, there are a number of often overlooked but important considerations when deploying this technology in a real-world scenario. In this paper, we present our efforts in developing a large-scale photo-tagging system for Flickr photo search. We discuss topics including how to select the tags that matter most to our users, develop lightweight, high-performance models for tag prediction, and leverage the power of large amounts of noisy data for training. Our results demonstrate that, for real-world datasets, training exclusively with noisy data yields performance nearly on par with the standard paradigm of first pre-training on clean data and then fine-tuning. We advocate for the approach of harnessing user-generated data in large-scale systems.

1 Introduction

Photos play a central role in our lives. On a daily basis, we pick up our phones, open the camera, and take photos. Searching our personal photos has become one of the most compelling consumer applications of deep learning. Our aim is to develop powerful image recognition models that can be used to power features like search or recommendations in consumer photography products like Flickr.

With deep neural networks being the de facto choice for image classification [8], training models with thousands of classes and millions of parameters currently relies on access to large datasets of annotated images, most commonly ImageNet [2], a crowdsourced dataset of 14 million images crawled from web search using WordNet [11] synsets that revolutionized the field, and still remains the largest public annotated dataset to date. However, such a dataset is not well suited for building models that can be deployed in consumer products such as Flickr. Users' interests span a larger variety of concepts, many of which are not part of ImageNet or even WordNet, while at the same time ImageNet is strongly biased towards photos where a single object appears in the center of the photo.

In this paper, we argue that it is possible to train better models *from scratch*, without any other source of clean/annotated data, using the annotations provided by our users via the photo titles, tags, and descriptions. This results in a simpler workflow than the standard paradigm of pre-training on a clean corpus (e.g. ImageNet) and fine-tuning for the specific classification task, especially when developing novel neural network architectures. We believe this is an important result as deep learning is applied to new domains where large manually labeled datasets may not be available or not allowed to be used for commercial purposes, and it is important to gain insights into the practical impact of label noise. We make the following contributions: 1) we show that it is possible to

*Work was performed during an internship with Yahoo.

train competitive models without access to “clean”, crowdsourced labels and by relying exclusively on user-provided data; 2) we present a principled method to select concepts for which we train classifiers; 3) we propose a low-computation model that is suitable for large-scale deployment; and 4) we discuss additional constraints that should be taken into consideration when deploying such models in consumer photography products such as Flickr.

2 Datasets & tag selection

At the heart of the success of deep neural networks for image classification is the availability of large datasets of annotated photos such as ImageNet [2], or the recently released Open Images dataset². While the former was created using web search queries and mostly features iconic images for each class, the latter, as well as the much smaller NUS-WIDE [1], COCO [9], SUN [20] and Visual Genome (VG) [7] datasets are primarily crawled from Flickr. In addition, these datasets feature a large overlap with the Yahoo Flickr Creative Commons 100M Dataset [18] (YFCC) dataset, one of the largest public multimedia datasets ever released. Unfortunately COCO and NUS-WIDE are rather small both in terms of number of images (a few hundred thousand) and number of tags (a few hundred) for facilitating supervised training of deep models. YFCC and Visual Genome, in contrast, were unconstrained by construction in terms of concepts and are able to provide a much higher number of tags, in the order of thousands.

We take a user-centric approach and train our models using photos’ tags, titles, and descriptions from the YFCC dataset. Although the labels may not always be accurate, our method is much more scalable than relying exclusively on manual annotations due to the cost and latency of crowdsourcing. In order to train classifiers for concepts most relevant to our users, we manually reviewed the top 10,000 tags ordered by how many users have used each tag at least once (we empirically looked at other measures of tag popularity and found this one to perform well). We excluded 1) number tags (e.g. “2014”); 2) location tags (e.g. “Paris”) that are best handled in conjunction with GPS information; 3) non-English tags (e.g. “chien”) that are handled through a separate NLP module; and 4) potentially offensive tags (e.g. “fat”, “old”, etc...). Our final vocabulary contains 4,562 tags and will be made available in the appendix on ArXiv. The 5 most popular tags are “sunset”, “beach”, “water”, “sky” and “night”. Examples of popular tags that are not present in ImageNet nor Open Images are “bokeh”, “burning man”, “diy”, “yum”, “light painting”, “star wars”, and “art deco”.

We evaluate our models on two manually annotated datasets: COCO and VG. We use the COCO validation set for testing, which contains 61 overlapping concepts. We treat the entire VG dataset as a test set and select as concepts all *objects* that appear more than 80 times and cover more than 2.5% area in the image. This results in the 903 concepts on which we report results in this paper, but could further be increased by a few hundred concepts if *attributes* are considered in addition to objects. Although this is a fraction of the tags we actually predict, this gives us the ability to report accurate results.

3 System description

3.1 Model architecture

Though the trend in the computer vision community has been to use deeper and more complex models to improve performance on ImageNet [14, 16, 4], computational complexity and model size often make these models impractical for industrial applications. When searching for optimal architectures we use ImageNet performance as our guide, as the large body of work on this dataset makes it easier to understand the impact of our design choices. Our overall model design draws inspiration from the layer replacement strategy used for the Constrained time Cost (CTC) models in [3], where the general approach is to substitute large filters (e.g., 5×5) with a cascade of smaller filters (e.g., 3×3).

In an effort to go deeper while remaining lean, we start with an initial model (YFNet-A) with 4 stages consisting solely of 3×3 convolutions other than the 7×7 convolution in the first layer. We reduce complexity further by factoring each 3×3 filter into a 3×1 followed by 1×3 convolution as in [17]. The resulting model, YFNet-B, enjoys the best performance on ImageNet, with $\sim 3\%$ higher

²<https://research.googleblog.com/2016/09/introducing-open-images-dataset.html>

Name	Stage-1	Stage-2	Stage-3	Stage-4
CTC-A	$(7, 64)/_2$	$(5, 128)$	$(3, 256) \times 3$	—
CTC-J	$(7, 64)/_2$	$(2, 128) \times 4$	$(2, 128) \times 4$	$(2, 2304) + (2, 256)$
YFNet-A	$(7, 64)/_2$	$(3, 128) \times 2$	$(3, 256) \times 3$	$(3, 512) \times 2 + (3, 256)$
YFNet-B	$(7, 64)/_2$	$(1 \times 3, 3 \times 1, 128) \times 2$	$(1 \times 3, 3 \times 1, 256) \times 3$	$(1 \times 3, 3 \times 1, 512) \times 2 + (1 \times 3, 3 \times 1, 256)$

Table 1: Configurations of the CTC and YFNet models. The notation (s, n) represents the filter size and the number of filters. “ $_2$ ” represents stride = 2 (default 1). “ $\times k$ ” means the same layer configuration is applied k times (not sharing weights). “+” means another layer is followed. All convolutional layers are with batchnorm and ReLU. The feature map sizes of stages 2, 3, and 4 are 36×36 , 18×18 , and 6×6 , respectively.

Name	Top-1	#FLOPs (M)	#Params (M)
VGG16	0.684	15470	138.3
ResNet-152	0.770	11300	60.2
GoogleNet	0.687	1582	7.0
AlexNet	0.571	1135	62.4
YFNet-A	0.632	1117	79.7
CTC-A	0.568	926	75.0
CTC-J	0.635	901	79.2
YFNet-B	0.664	877	77.9

Table 2: Comparison with well-known models on ImageNet ordered by FLOPs. Top-1 accuracy is measured on the validation set using single center crop. Numbers of operations and parameters are in millions.

top-1 accuracy than CTC-J, despite having lower computational complexity (877 vs 901 million FLOPs for CTC-J). In Table 2 we compare the performance of our best model with other state-of-the-art architectures. We see that YFNet-B significantly outperforms AlexNet for approximately the same computational cost. Although top-1 accuracy is lower than GoogleNet [16] and ResNet [4], our model is $\sim 1.8x$ and $\sim 12.9x$ faster, respectively.

3.2 Tag prediction in the wild

There are many recent efforts that have dealt with training from noisy labels [15, 6, 5, 21, 12]. These works however usually model label noise unrealistically, *e.g.*, through simple label flips or the existence of outlier images. In our own analyses, we have observed that the most common source of noise in user-generated data is, in fact, missing labels. Here we simply train our models using a randomized softmax that has been shown to perform well for multilabel classification [6]. In order to study the impact of dataset size, we generate datasets with $k \in \{1000, 2000, 4000\}$ samples per tag. The k samples per tag are selected by taking the top scoring photos using a linear combination of the *tf-idf* matches between the tag and the photo’s title, description, and tags. Images belonging to COCO or VG are excluded.

Name	Train	Dataset		Performance (mAP)	
			Fine-tune	COCO	VG
CTC-J	ILSVRC-1K	YFCC-1K		0.376	0.082
YFNet-B	ILSVRC-1K	YFCC-1K		0.433	0.104
YFNet-B	ILSVRC-1K	YFCC-2K		0.449	0.111
YFNet-B	ILSVRC-1K	YFCC-4K		0.462	0.115
YFNet-B	YFCC-1K	—		0.423	0.098
YFNet-B	YFCC-2K	—		0.437	0.108
YFNet-B	YFCC-4K	—		0.451	0.113

Table 3: Results on COCO and VG datasets. We used 25 epochs for fine-tuning and 35 epochs for training from scratch.

We show in Table 3 the COCO and VG mean average precision scores for models fine-tuned from the weights of a model pre-trained on ImageNet and trained from scratch. We observe that, as with the ImageNet dataset, YFNet-B significantly outperforms CTC-J. As expected, performance improves with the number of training examples, further validating the importance of data in training deep neural networks. Perhaps more surprisingly, the performance only drops from 0.115 to 0.113 between a model pre-trained on ImageNet and a model trained from a random initialization. This demonstrates that it is possible to train competitive image recognition models without access to “clean”, crowdsourced data. As deep learning is applied to new domains, it is worth harnessing all sources of labels, even if they are noisy, before assembling a crowdsourced dataset. We think that training models on YFCC and testing on VG is a good benchmark for research in this area.

4 Deployment

The primary goal when developing our classifiers is to improve features in products such as Flickr search or photo recommendations. It is critical to have a separation of concerns between the core recognition technology and downstream applications. Otherwise, spurious dependencies make these systems harder to maintain, create technical debt, and ultimately slow down innovation. In order to achieve such a separation, the classifiers’ output scores ought to be:

Interpretable: An application developer needs to achieve the correct operating point in the precision/recall trade-off in order to achieve product requirements. For example, recall may be more important than precision for personal photo search. The most natural output score is the posterior probability of a tag being present in an image, e.g. $p(dog|image)$. Also, having an interpretable representation makes it possible to deactivate a classifier in case we run into unacceptable edge-cases.

Consistent across tags: A score of 0.8 for the “cat” classifier should have the same meaning as a score of 0.8 for the “flower” classifier. By using the posterior probability as the classifier’s output for each tag, we ensure consistency in the interpretation of the scores.

Consistent across versions: Image recognition is evolving fast and we need the ability to release improved versions of our system without having to modify downstream components. For example, if classifier scores in a new version had a different dynamic range, complex logic would be required in order to jointly rank photos tagged by different versions.

We transform the pre-softmax activations into a posterior probability by using a sigmoid function where we estimate a bias term for each class. It is unfortunately difficult to estimate the bias as we are in a Positive/Unlabeled (P/U) setting [13]. In practice, photos from YFCC are not exhaustively labeled and therefore many negative examples for a given tag may in fact be positive. It has been shown that it is unfortunately not possible to accurately estimate the posterior probability unless the empirical distribution of the class is known [19]. As a result, we use a web user interface to review every classifier and adjust the bias. Though this process is somewhat cumbersome, when deploying these algorithms in our products, we think that manual calibration remains critical and further automation of this calibration step is an area of ongoing research.

5 Conclusion and future directions

In this paper we aimed to shed light on the process of developing a large-scale, state-of-the-art tagging system for photo search. We have identified and discussed the most relevant engineering challenges including tag selection, training dataset creation, as well as development, training, and calibration of the classification model. We have demonstrated the ability to adapt the leading models from the computer vision community to yield novel architectures that perform well in the consumer photo domain, where the scale of the data and noisiness of the annotations present significant challenges. With the growing number of photos being uploaded, we believe that training with noisy labels from corpora like YFCC is an important problem for large-scale image classification and is highly applicable in many commercial domains. We also consider Visual Genome, with its plethora of classes, a well-suited test bed for such a task, and we are currently expanding test classes to include not just entities but also attributes and relationships. We are also exploring more expressive loss functions with an explicit noise model, and on the model architecture side, fully-convolutional networks [10] which offer the promise of being better able to recognize small but relevant visual concepts within a photo.
